

# AETHER DEFENSE INFRASTRUCTURE — INTERCONNECTED THREAT TELEMETRY (Q2)

[RESTRICTED CLASSIFICATION — INTERNAL CYBERSECURITY OPERATIONS TIER]

## 1. THREAT LANDSCAPE OVERVIEW

During the second operational quarter, Aether Defense networks observed a marked escalation in distributed state actor activities. Automated edge firewalls mitigated multiple high-velocity reconnaissance passes. Our localized endpoint detection configurations contained 98.4% of hostile payloads prior to lateral staging attempts.

## 2. DISTRIBUTED EDGE ATTACK VECTORS (TABLE 3.4)

The following relational database logging sequence summarizes the primary threat vectors, packet entry points, and total observed telemetry volume:

| Vector Category   | Target Gateway                | Flagged Count |
|-------------------|-------------------------------|---------------|
| Brute-Force SSH   | Public Web DMZ Node Alpha     | 142,500       |
| API SQL-Injection | Customer Checkout Endpoint    | 89,210        |
| Malicious Payload | Remote VPN Ingress Core       | 12,450        |
| Phishing Webhook  | Internal Corporate Mail Relay | 4,120         |

## 3. VULNERABILITY MITIGATION SPECTRUM (CHART 9 VISUAL ANALOGUE)

An empirical evaluation of Chart 9 (Vulnerability Patch Cycles) highlights an isolated visual latency gap in our internal staging cycle. Remediation times for critical CVE metrics temporarily extended out to 18 days due to internal hardware dependency conflicts associated with legacy container runtimes. Mitigation times normalized back to 2 days following our global cluster migration to native Kubernetes orchestration engines.
